What you need to know:

We shall use the notation $a|b$ to mean a is a divisor of b . The definition of $x \equiv y \pmod{m}$ is that $m|(x - y)$.

Questions:

Modular arithmetic:

- (a) What is the set of all x satisfying $x \equiv 2 \pmod{5}$?
(b) Prove that if $a_1 \equiv b_1 \pmod{m}$ and $a_2 \equiv b_2 \pmod{m}$, then $a_1 + a_2 \equiv b_1 + b_2 \pmod{m}$.
(c) Prove that if $a \equiv b \pmod{m}$ then $ka \equiv kb \pmod{m}$, where $k \in \mathbb{Z}$.
(d) Prove that if $a \equiv b \pmod{m}$ then $a^k \equiv b^k \pmod{m}$, where $k \in \mathbb{Z}^+$.

One can calculate the last digit of an integer, n , by calculating what $n \pmod{10}$ is.

- $11 \equiv 1 \pmod{10}$, so what is the last digit of 11^{1000} ?
- What is the last digit of 12^{1000} ?
- Prove that a number is divisible by 9 if and only if the sum of its digits is also divisible by 9.

Irrationality:

- (a) Prove that $\log_2 3$ is irrational. (Hint: proof by contradiction.)
(b) Prove that $\sqrt{2}$ is irrational.
(c) Why does a similar proof not work for $\sqrt{4}$?

Prime numbers:

- (a) Prove there is no largest prime number.

Fermat's little theorem states that if p is a prime number, then for any integer x , $x^p \equiv x \pmod{p}$.

(b) Prove Fermat's little theorem. (Hint: proof by induction.)

When massive primes are found, they are often Mersenne numbers, which are integers of the form $2^n - 1$, where n is an integer. A Mersenne prime is a number which is both a Mersenne number and a prime number.

(c) Suppose a and p are positive integers. Prove that if $a^p - 1$ is prime, then either $a = 2$ or $p = 1$.

(d) Prove that if $2^p - 1$ is prime, then p is prime. (Hint: contrapositive.)
